Abstract

Aims: Qualitative analysis of prepared mucoadhesive polymeric (Carbopol934) suspension of Norfloxacin was performed with the aim of developing an oral controlled release gastro-retentive dosage form. **Methods:** The characterization of ultrasonicated formulation was carried out by Fourier Transform Infrared Spectroscopy (FTIR), Raman Spectroscopy, X-ray powder diffraction (XRD) and Scanning electron microscopy (SEM) analyses. FTIR (400 cm^{-1} to 4000 cm^{-1} region) and Raman (140 to 2400 cm^{-1} region) spectra were used for interpretation. XRD data of pure drug, polymer and the formulation were obtained using a powder diffractometer, scanned from a Bragg's angle (2θ) of 10˚ to 70˚. The dispersion of particle was observed using SEM techniques. **Results:** The results from FTIR and Raman Spectroscopic analyses suggested that in formulation, the carboxylic groups of Norfloxacin and hydroxyl groups of C934 undergo chemical interaction leading to esterification and hydrogen bonding. The XRD data suggested that the retention of crystalline nature of Norfloxacin in the formulation. The SEM image analysis indicated that in the formulation maximum particles exhibited network like structure to produce pseudoplastic flow. **Conclusion:** From our analysis it can be concluded that homogeneous, uniformly dispersed, pharmaceutically

stable controlled release Norfloxacin suspension was prepared which possessed better bioavailability and penetration capacity.

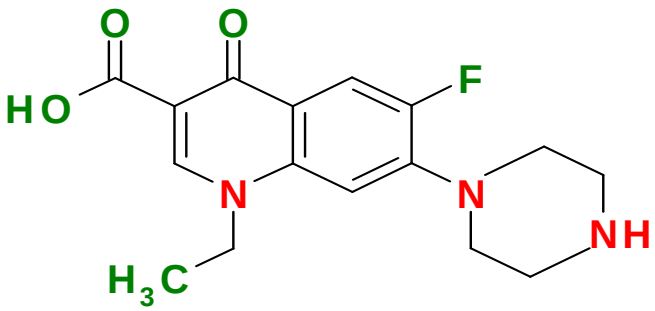
Keywords: Carbopol934, FTIR, Mucoadhesive suspension, Norfloxacin, Raman spectroscopy, XRD.

Introduction

Oral controlled release (CR) dosage forms (DFs) have been developed over the past three decades due to their considerable therapeutic advantages such as ease of administration, patient compliance and flexibility in formulation. Incorporation of the drug in a controlled release - gastro retentive dosage forms (CR-GRDF) can remain in the gastric region for several hours, which would significantly prolong the gastric residence time of drugs and improve their bioavailability, reduce drug wastage and enhance the solubility of drugs[1].

Several approaches are currently used to prolong gastric retention time. Since the goals of controlled drug delivery are to conserve and maintain effective drug concentration, eliminate night time dosage, improve compliance and decrease side effects, in the present study polymeric bioadhesive delayed gastric emptying devices have been explored[2].

Norfloxacin (Norflox), 1-ethyl-6-fluoro-1,4-dihydro-4-oxo-7-(1-piperazinyl)-3-quinolone carboxylic acid, is a second generation fluoroquinolone **(Fig 1)**. It inhibits the enzyme deoxyribonucleic acid (DNA) gyrase preventing DNA and protein synthesis. It requires multiple administration of drug, leading to fluctuation in plasma concentration of the drug[3].



Norfloxacin

Figure 1: Chemical Structure of Norfloxacin.

The polymer in the formulation interacts with the mucosal component, increasing the contact time with the mucosa at the site of absorption. The prolonged contact time has been attributed to rheological properties of formulation, which delays its clearance from the mucosa[4]. In the present study, the polymer used is Carbopol934 (C934), which consists of chains of polyacrylic acid[5] **(Fig 2)**. Carbopol polymers are considered as environmentally responsive polymers or "smart gels" which produce pseudo fed state, thereby reducing peristaltic contraction[6,7] that alters their swelling behaviour upon exposure to an external stimulus such as change in pH [8,9], temperature [10], light, or electric field which provides on-off release[11-14]. In stomach, Carbopol polymer forms hydrogen bonding with the drug and also with the polysaccharides or proteins of mucosa, which is probably the major mechanism for bioadhesion. In addition, under alkaline condition of the intestine, Carbopol polymers are very highly swollen[15].

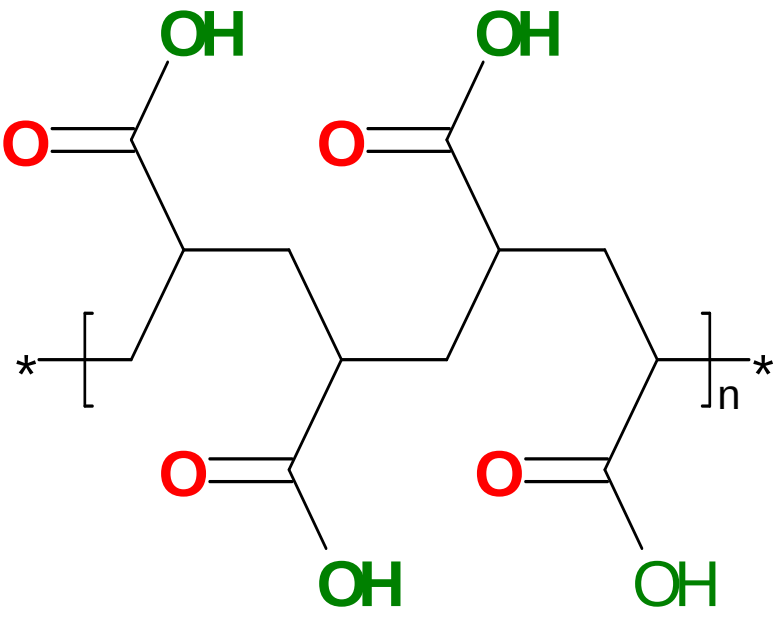


Figure 2: Chemical Structure of Carbopol Polymer (Polyacrylic acid)

Carbopol934 may form a complex with the low solubility drug like Norfloxacin. The interaction between Norflox and C934 can be determined by several methods such as Fourier Transform Infrared (FTIR) Spectroscopy, Raman Spectroscopy, etc. To know the different functional groups and highly polar bonds of both pure Norflox and C934, and their chemical interactions in the mucoadhesive suspension, FTIR analysis was conducted. However, their backbone structures and symmetric bonds were checked by Raman spectroscopy. Although it is known that Raman

and FTIR are complementary vibrational spectroscopic methods, there are band intensity differences between the two techniques. That is why both FTIR and Raman Spectroscopic analyses were conducted.

The X-ray diffraction (XRD) method has become one of the most useful tools for qualitative characterization of crystalline compounds both in formulation and in pure form of the drug[16]. It is known that increased dissolution rate and delayed release of drug from dosage forms occur with increase in crystallinity[17,18]. XRD study is important because any change in the morphology of polymers, or in the crystalline state of active ingredients in the final product, resulting from the manufacturing process, could influence a drug's bioavailability[19].

Since the SEM image analysis gives insight into the rheological properties and pharmaceutical stability of the suspension, SEM image analysis of suspension was carried out[20-22].

Therefore, to obtain more detailed information about chemical interaction between Norfloxacin and C934, FTIR and Raman analyses were carried out[23,24]. Moreover, considering the bioavailability, stability and degree of dispersion of the particles present in the formulation, XRD and SEM analyses were conducted[9,16,20-22]. Considering all the positive aspects of different qualitative analyses, in the present investigation we performed FTIR analysis, Raman Spectroscopy, XRD and SEM studies of the mucoadhesive suspension.

Materials and Methods

Materials:

The following materials were used: Norfloxacin was obtained from Dr. Reddy's Lab, Hyderabad, India, as a gift sample. Carbopol934, Pluronic F68 and Soya lecithin were purchased from Himedia Laboratories Pvt. Ltd., India. Glycerol, Mehtyl praraben, Propyl paraben, Sorbitol solution I.P. and Sucrose were kindly supplied by Cosmo Chem. Laboratory, India. Ultra pure water was obtained from a Millipore Milli-Q UV water filtration system.

Methods:

Formula for Preparation of Mucoadhesive Suspension-

Formula for Preparation of Suspension Base-

(Percentage with respect to Norfloxacin)

Carbopol934	5%

Pluronic F 68	5%
Soya lecithin	1%
Sorbitol Solution (80%)	7.2%
Glycerin	0.8%
Methyl paraben sodium	0.015%
Propyl paraben sodium	0.08%
Simple Syrup IP	40%
Purified water qs up to	100ml

Concentration of Norfloxacin used in the Formulation-

500mg/25ml

Preparation of Formulation

1. Preparation of Bulk A

In a beaker, 6 ml water was taken and it was heated up to 80° C. Sucrose (10 gm) was added to that water with continuous stirring. The temperature was monitored in such a way so that it should not fall below 70° C, till the sucrose was completely dissolved. The prepared syrup was cooled properly at room temperature and kept overnight. Syrup was filtered using 120 mesh nylon cloth.

2. Preparation of Bulk B

Five millilitre of Ultra pure water was taken in a beaker to which 1.8 ml of sorbitol solution and 0.2 ml glycerin were added. The mixture was stirred properly. Pluronic F 68 (5%), soya lecithin (1%) and C934 (5%) in w/w of drug were added to this solution with continuous stirring.

3. Preparation of Mucoadhesive Suspension and Ultrasonication

Five millilitre of water was taken in another beaker to which 500 mg of Norfloxacin was added. To the drug suspension, the bulk B and bulk A were added with continuous stirring. Methyl paraben sodium (0.015%w/v) and Propyl paraben sodium (0.08%w/v) were added as preservatives. The volume was made up to 25 ml by Ultra pure

water. The pH was adjusted to 5.5. Homogenization was carried out for at least 20 min by ULTRASONIC HOMOZENIZER LABSONIC^{R} M (SARTORIUS), having operating frequency 30 KHZ and line voltage 230 V/50 HZ, using the probe made up of Titanium of diameter 7 mm and length 80 mm. The setting knob "cycle" was adjusted to 0.8, indicating sound was emitted for 0.8 s and paused for 0.2 s. In this manner, we could expose our sample with 100% amplitude, while reducing the heating effect to 80%. This LABSONIC^{R}M generates longitudinal mechanical vibrations with a frequency of

30,000 oscillations / s (30 KHZ). The probes bolted to the sound transducer were made of high-strength Titanium alloys, built as λ /2 oscillators. It amplified the vertical oscillation, and transferred the ultrasonic energy via its front surface with extremely high power density into the sample that was to be subjected to ultrasonic waves. In our study, stress applied was sound wave and in addition, mild rise in temperature of the sample occurred during ultrasonication which helped in the homogenization of the suspension. Some portion of the homogenized suspension was kept for Raman Spectroscopic analysis and SEM study. The remaining portion of the suspension was sprayed on to an aluminum slip with the aid of an atomizer. The fine droplets were dried overnight at room temperature and the solid samples were then collected and powdered. The sample was then divided into two parts – one part was for FTIR analysis, and the other part was used for XRD study.

Fourier Transform Infrared Spectroscopy

FTIR analysis was performed by FTIR Spectrophotometer interfaced with infrared (IR) microscope operated in reflectance mode. The microscope was equipped with a video camera, a liquid Nitrogen-cooled Mercury Cadmium Telluride (MCT) detector and a computer controlled translation stage, programmable in the x and y directions. Solid powder samples were oven dried at around 30°C, finely crushed, mixed with potassium bromide (1:100 ratio by weight) and pressed at 15000 psig (using a Carver Laboratory Press, Model C, Fred S. carver Inc., WIS 53051) to form disc. The detector was purged carefully using clean dry nitrogen gas to increase the signal level and reduce moisture. The spectra were collected in the 400 cm^{-1} to 4000 cm^{-1} region with 8 cm^{-1} resolution, 60 scans and beam

spot size of 10 μm-100 μm[25-27]. The FTIR imaging in the present investigation was carried out using a Perkin Elmer Spectrum RX.

Raman Spectroscopic Analysis

The Raman system R-3000 instrument (Raman systems INC.USA), a low resolution portable Raman Spectrometer using a 785 nm solid state diode laser, was adjusted to deliver 250 mw to the sample having spectral resolution 10 $cm^{-1}$and 12 v dc/5A power supplies and USB connectivity. The solid powder samples i.e., both pure drug and polymers were enclosed in plastic poly bags and tested directly. For our study, the fibre optic sampling probe was directly dipped into the formulation (prepared as per the above mentioned procedure) to collect the spectra at room temperature. The interference of the outside light was also prohibited to prevent photon shot noise. The spectra were collected over the wave number range from 140 to 2400 cm^{-1}.

X-Ray Diffractometry

XRD measurements were obtained using the Philips X'Pert on powder diffraction system (Philips Analytical, The Netherlands) equipped with a vertical goniometer in the Bragg-Brentano focusing geometry. The X-ray generator was operated at 40 kV and 50 mA, using the CuKα line at 1.54056 Å as the radiation source. The powdered specimen was packed and prepared in a specimen holder made of glass. In setting up the specimen and apparatus, co-planarity of the specimen surface with the specimen holder surface and the setting of the specimen holder at the position of symmetric reflection geometry were assured. The powders were passed through a 100 mesh sieve and were placed into the sample holder by the side drift technique[28]. In order to prepare a sample for analysis, a glass slide was clipped up to the top face of the sample holder so as to form a wall. Each powder was filled into the holder and tapped gently. Each sample was scanned from 10˚ to 70˚ (2θ) and in stage sizes of 0.020; count time of 2.00 s, using an automatic divergence slit assembly and a proportional detector. The samples were scanned at 25° C. Relative intensities were read from the strip charts and corrected to fix slit values.

Scanning Electron Microscopy

In order to examine the particle surface morphology and shape, SEM was used. The mucoadhesive suspension (as mentioned above) was sprayed on to an aluminum slip with the aid of an atomizer. The fine droplets were dried overnight and it was used for SEM analysis[29]. The samples were given a conductive coating (using Pt, of about 600 A^0 thick), using sputter ion coater and examined with SEM (JEOL JSM-6480LV) equipped with a backscattered electron detector for imaging and EDXA for elemental analysis. In this method, a focused electron beam is scanned over the sample in parallel lines. The electrons interact with the sample, producing an array of secondary effects, such as back-scattering, that can be detected and converted into an image. The image can then be digitalized and presented to an image analyzer, which uses complex algorithms to identify individual particles and to record detailed information about their morphology.

Results

The infrared spectra are recorded on Fourier Transform Spectrometer in the mid –infrared region (MIR) within the range (400-4500 cm^{-1})[30]. Due to the complex interaction of atoms within the molecule, IR absorption of the functional groups may vary over a wide range. However, it has been found that many functional groups give characteristic IR absorption at specific narrow frequency range. Multiple functional groups may absorb at one particular frequency range but a functional group often gives rise to several characteristic absorptions. Thus, the spectral interpretations should not be confined to one or two bands only; actually, the whole spectrum should be examined.

While the FTIR bands at 4000-1300 cm^{-1} represented functional group region, the appearance of strong absorption bands in the region of 4000 to 2500 cm^{-1} was due to stretching vibrations between hydrogen and some other atoms with a mass of 19 or less. The O-H and N-H stretching frequencies were in the 3700 to 2500 cm^{-1} region with various intensities. Hydrogen bonding has a significant influence on the peak shape and intensities, generally causing peak broadening and shifts in absorption to lower frequencies. The C-H stretching vibration occurred in the region of 3300 to 2800 cm^{-1} [25,26].

In FTIR spectra of Norfloxacin, one prominent characteristic peak was found between 3550 and 3500 cm^{-1}, which was assigned to stretching vibration of OH group and intermolecular hydrogen bonding by single bridge. A band at 3500 to 3300 cm^{-1} suggested the NH stretching vibration of the imino-moiety of piperazinyl groups. The peak at 2750-2700 cm^{-1} indicated the presence ethyl group. The band at 2500 cm^{-1} was due to the υOH group of the carboxylic acid. The peak at 1700 cm^{-1} represented the carbonyl C=O stretching i.e., $\upsilon_{C=O}$. The band at 1650 to 1600 cm^{-1} was assigned to υN-H bending vibration of quinolones. The peaks at 1500 to 1450 cm^{-1} represented υ_{O-C-O} of acids and at 1300 to 1250 cm^{-1} suggested bending vibration of O-H group, which indicated the presence of carboxylic acid. In addition, a strong absorption band between 1050 and 1000 cm^{-1} was assigned to C-F group. The peak in the region 950-900 cm^{-1} suggested the δNH bending vibration of amines. The band at 800 cm^{-1} was due to the meta distribution of the aromatic protons **(Fig 3 and Table 1)**[26,31,32].

Table-1: Prominent FTIR peaks of Norfloxacin.

PEAKS(cm-1)	**GROUPS**	**PEAK ASSIGNMENT**
3550-3500	Hydroxyl group	Intermolecular H -bonding by single bridge
3500-3300	Imino-moiety of Piperazinyl groups	NH stretching vibration
3000-2950	Aromatic,cyclic enes	υ=CH & Ar-H
2750-2700	Ethyl group	υCH_2
2500	Acid group	υOH group
1700	Carbonyl of acids	υC=O stretching vibration

1650-1600	Quinolones	υN-H bending vibration
1500-1450	O-C-O group of acid	υ_s stretching vibration of O-C-O group
1300-1250	Hydroxyl group	δO-H bending vibration
1050-1000	C-F groups	υC-F
950-900	Amines	δNH bending vibration
800	Aromatic m – distribution	δAr-H

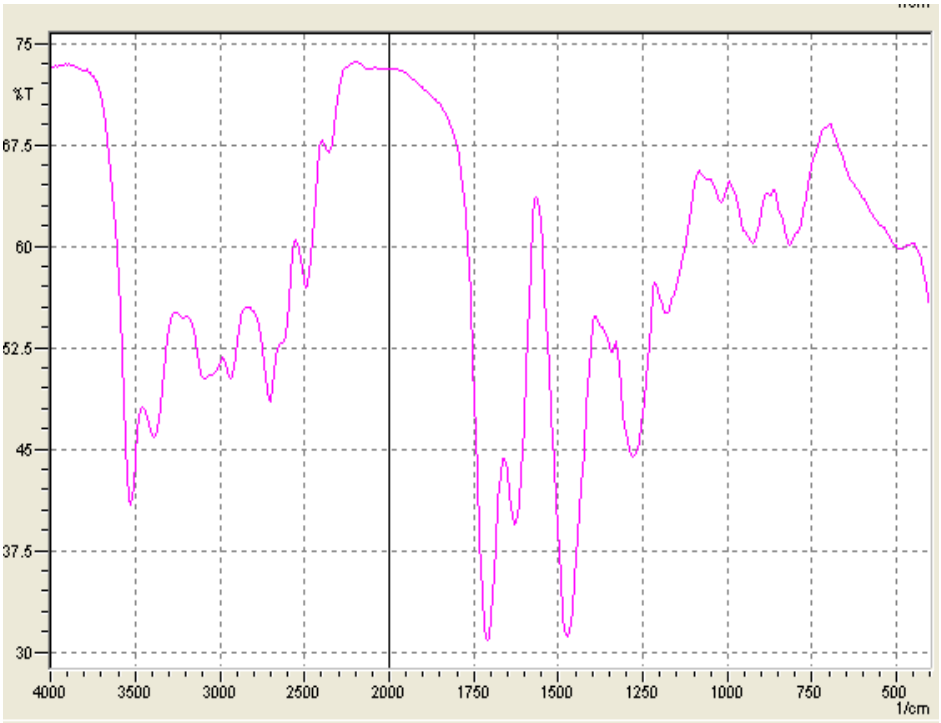

Figure 3: FTIR peaks of Norfloxacin

In case of C934, the FTIR spectra having peak between 3000 and 2950 cm^{-1} represented OH stretching vibration, i.e., υ_{O-H} and intramolecular hydrogen bonding **(Fig 4)**. The prominent band between 1750 and 1700 cm^{-1} was assigned to carbonyl C=O stretching vibration i.e., $\upsilon_{C=O}$. While the peak at 1450 to 1400 cm^{-1} was for υ_{C-O} / δ_{O-H}, the band at 1250 to 1200 cm^{-1} suggested to υ_{C-O-C} of acrylates[26,30]. The ethereal cross linking, proved by prominent peak at 1160 cm^{-1}, indicated stretching vibration of υ_{C-O-C} group. The band between 850 and 800 cm^{-1} was for out of plane bending of =C-H i.e., $\delta_{=C-H}$ [25,30] **(Table 2)**.

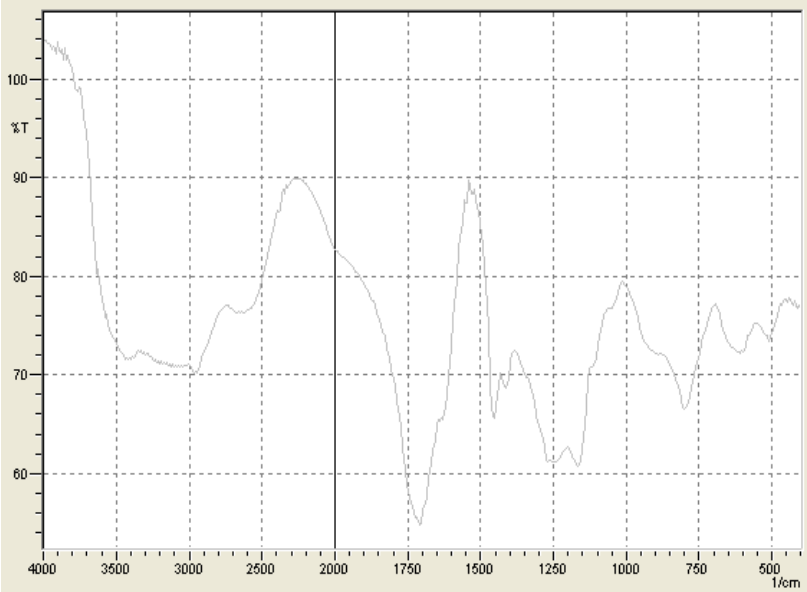

Figure 4: FTIR peaks of Carbopol934

Table-2: Prominent FTIR peaks of Carbopol934.

PEAKS(cm-1)	GROUPS	PEAK ASSIGNMENT
3000-2950	Hydroxyl group	O-H stretching vibration, intramolecular H-bonded
1750-1700	C=O group of acids	$\upsilon_{C=O}$ stretching vibration
1450-1400	Carbonyl group of acids	υ_{C-O}
1250-1200	Acrylates	C-O-C stretching vibration
1160	Ethereal C-O-C group	Stretching vibration of C-O-C group
850-800	Aromatics & enes	=C-H out of plane bending vibration

In the FTIR spectra of formulation containing both Norflox and C934, the prominent band, found between 3550 and 3400 cm^{-1}, was assigned to υ_{O-H} and polymeric hydrogen bonding **(Fig 5)**. The peak at 2600-2500 cm^{-1} represented the υ_{O-H} of carboxylic acid i.e., strong intermolecular hydrogen bonding. The band from 1650 to 1600 cm^{-1} was assigned to $\upsilon_{C=O}$ i.e., carbonyl stretching vibration. A prominent peak at 1500 - 1450 cm^{-1}(w) was for υ_{C-O} / δ_{O-H}. The band from 1300 to 1250 cm^{-1} was assigned to υ_{C-O-C} of acrylates. The peak between 1100 and 1000 cm^{-1} represented υ_{C-F} groups. The band at 800 cm^{-1} indicated the meta distribution of δ_{Ar-H} group [25,26,30] **(Table 3)**.

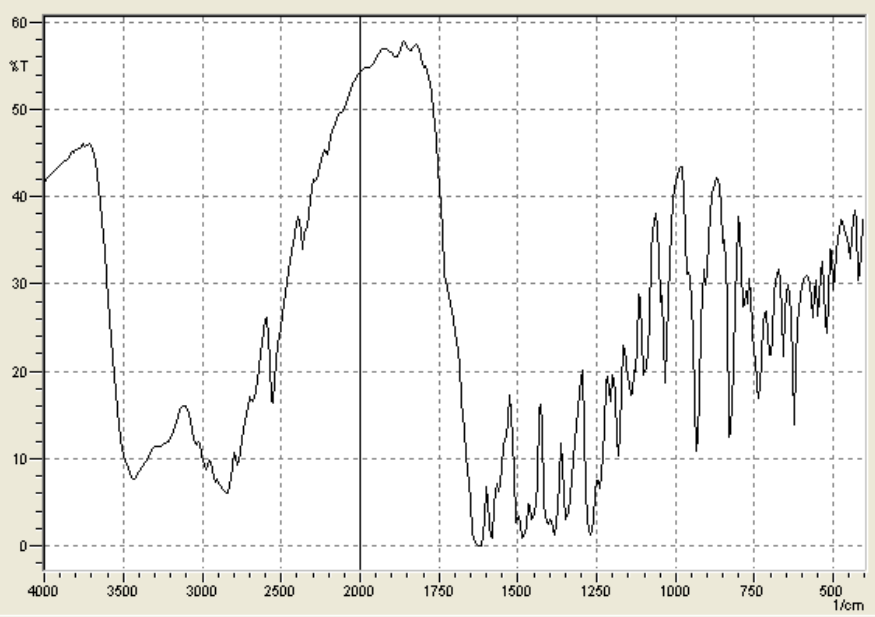

Figure 5: FTIR peaks of Norfloxacin Mucoadhesive Formulation

Table-3: Prominent FTIR Peaks of Norfloxacin Mucoadhesive Formulation.

PEAKS(cm-1)	GROUPS	PEAK ASSIGNMENT
3550-3400	Hydroxyl group	Polymeric H -bonding
2650-2500	Hydroxyl group of carboxylic acid	Strong Intermolecular H-bonding
1650-1600	O-C-O group of acid	υ_{as} stretching vibration of O-C-O group
1500-1450	O-C-O group of acid	υ_{s} stretching vibration of O-C-O group

1300-1250	Acrylates & esters	C-O-C stretching vibration
1100-1000	C-F groups	υC-F
800	Aromatic m – distribution	δAr-H

By Raman spectroscopy of Norfloxacin, the prominent Raman shifts have been observed at 485.6, 872.7, 1418.5 and 1655.1 cm^{-1} **(Fig 6)**. The Raman shifts at 485.6 cm^{-1} indicated strong bending vibration of C-C of the aliphatic chain and C-N stretching vibration of piperazinyl group [33-35]. The band at 872.7 cm^{-1} represented the symmetric stretching vibration of C-F group[36]. The peak at 1418.5 cm^{-1} was due to symmetric stretching vibration of O-C-O group of carboxylic acid and methylene deformation mode of the piperazinyl group[37]. A band at 1655.1 cm^{-1} was for symmetric stretching of the carbonyl group $\upsilon_{C=O}$ of the pyridone moiety, the stretching vibration of (C-C) aromatic ring chain. In addition, it (peak at 1655.1 cm^{-1}) also indicated the $N^{+}H_2$ scissoring of piperzinyl group[33,37-40] **(Table 4a)**.

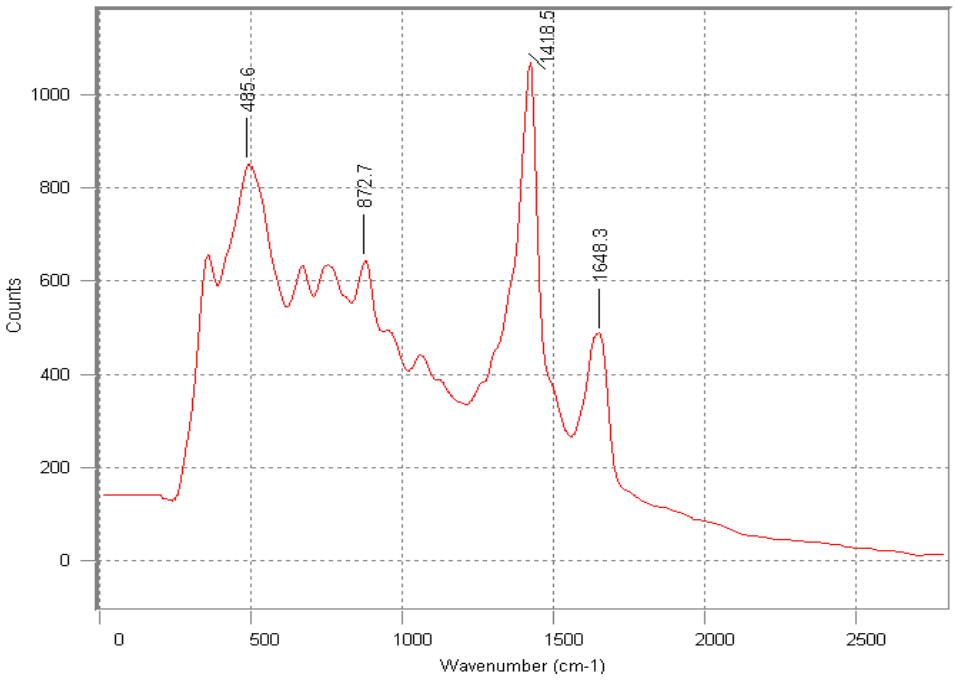

Figure 6: Raman Shifts of Norfloxacin

The characteristic prominent Raman bands for C934 were observed at 350, 514.31, 872.69 and 1335.03 cm^{-1} **(Fig 7)**. The bending vibration of C-C-O group was indicated by the Raman shift at 514.31 cm^{-1}. The band at 872.69 cm^{-}

[1] was due to stretching vibration of C-O-C for acrylates and carboxylic acid. The Raman band at 1335.03 cm^{-1} was assigned to symmetric vibration of O-C-O of acids[33] **(Table 4b)**.

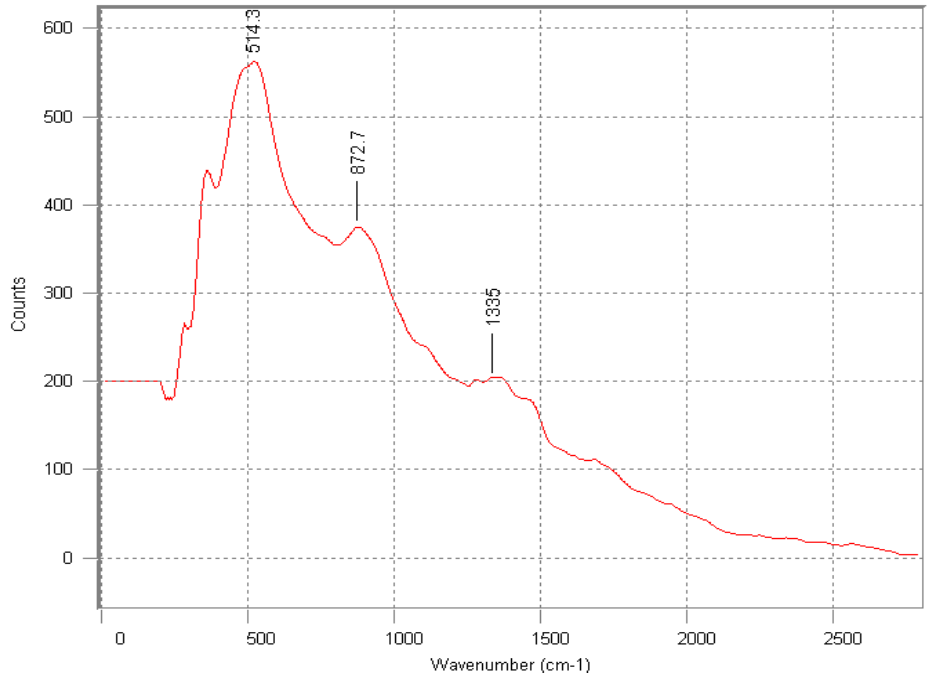

Figure 7: Raman Shifts of Carbopol934.

Table-4: Raman Shifts of pure Drug, Polymer and Formulation.

a) Prominent Raman Shifts of Norfloxacin	
Raman Shifts(cm^{-1})	**Functional Groups / Vibrations**
485.6	Strong $\delta_{(CC)}$ aliphatic chain and C-N stretching vibration
872.7	Symmetric vibration of C-F bond
1418.5	$\upsilon_{S\ O\text{-}C\text{-}O}$ and methylene deformation of the piperazinyl group
1655.1	υ_s of C=O group of pyridone moiety and N^+H_2 scissoring of piperzinyl group
b) Prominent Raman Shifts of C934	
Raman Shifts(cm^{-1})	**Functional Groups / Vibrations**

350	Strong $\delta_{(CC)}$ aliphatic chain
514.31	C-C-O bending vibration
872.69	$\upsilon_{(C\text{-}O\text{-}C)}$ of acrylates
1335.03	$\delta_{(CH3)}$ medium
c) Prominent Raman Shifts of Norfloxacin Mucoadhesive Formulation	
Raman Shifts(cm^{-1})	**Functional Groups / Vibrations**
338.8	δ(CC) aliphatic chain
900-800	Symmetric stretching vibration of both C-F group C-O-C group for acrylates and esters
1343.2	υ_sO-C-O
1550	υ_{as}O-C-O
1850-1700	υC=O medium

In the formulation containing both Norflox and C934, the Raman peak at 338.8 cm^{-1} represented bending vibration of δCC of aliphatic chain **(Fig 8)**. The band at 900-850 cm^{-1} was assigned to symmetric stretching vibration of both C-F group and C-O-C group for acrylates and esters. The peak at 1343.2 cm^{-1} suggested for symmetric stretching vibration of O-C-O group. The band at 1550 cm^{-1} was due to asymmetric stretching vibration of O-C-O group. The peak at 1850 to 1700 cm^{-1} was the characteristic of stretching vibration of carbonyl group of esters[33,40] **(Table 4c)**.

All the high intensity peaks (relative intensity) observed in the XRD pattern of the pure Norflox were compared with its mucoadhesive polymeric suspension **(Tables 5 and 6)**. Both the polymeric suspension and pure Norflox were found to show sharp XRD peaks but their XRD patterns are different **(Fig 9-11)**. Identification of a structure from its powdered diffraction pattern is based upon the position of peaks and their relative intensities. Each XRD pattern is characterized by the interplanar d- spacing and the relative intensities (I/I_0) of the three strongest peaks in the pattern under the Hanawalt system. The relative intensities and heights of three prominent peaks of the

formulation were less than those of pure Norflox **(Table 5)**. Moreover, complete diffraction patterns of both pure Norfloxacin and the formulation can be seen in **Table 6**.

From the SEM image analysis of suspension, it has been found that particles had network like structure **(Fig 12)**. Due to that we could not perform particle size distribution analysis. For the same reason we were unable to determine length/width ratios (aspect ratio) of individual particles satisfactorily.

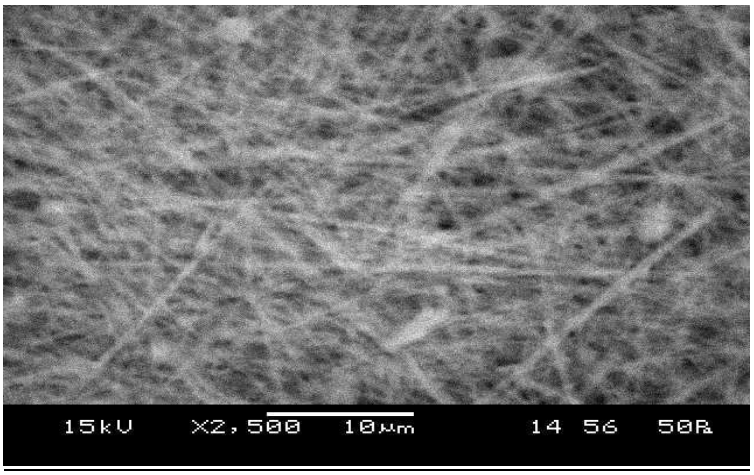

Figure 12: SEM of Norfloxacin Mucoadhesive Formulation.

Discussion

When FTIR radiation falls on a molecule, it may be absorbed, reflected or transmitted. Absorption leads to the FTIR spectrum, while reflection leads to scattering which is utilized in Raman Spectroscopy[25]. In addition, Infra red (IR) absorption of the functional groups may vary over a wide range. However, it has been found that many functional groups give characteristics IR absorption at specific narrow frequency range.

Infra red (IR) absorption of the functional groups may vary over a wide range. However, it has been found that many functional groups give characteristics IR absorption at specific narrow frequency range[25,26].

In case of FTIR spectra of Norflox, prominent peaks for $\upsilon_{\mathbf{C\text{-}O}}$ / $\delta_{\mathbf{O\text{-}H}}$ and $\upsilon_{C=O}$ indicated the presence of –CO-, -CHO and -COOH groups **(Fig 3)**. The presence of above groups could be confirmed by fermi resonance bands for –CHO, $\upsilon_{\mathbf{C\text{-}O\text{-}C}}$ bands for esters and absence of these two for ketones. This suggested the existence of –COOH group in Norflox molecule **(Table 1)**.

Another probability of intermolecular hydrogen bonding may be due to prominent FTIR peaks between 3550 and 3500 cm^{-1}. The band at 3500-3300 cm^{-1} indicated the presence of piperazinyl group. The presence of ethyl group was confirmed by the appearance of a sharp peak at 2750-2700 cm^{-1} [26,41]. The peak at 1650-1600 cm^{-1} was due to the quinolone moiety of Norfloxacin. The bending vibration of O-H group showed medium to strong band in the region around 1300-1250 cm^{-1}, which confirmed the presence of COOH group. Here, the FTIR peak at 950-800 cm^{-1} suggested the probability of bending of NH group. The peak at 1050-1000 cm^{-1} indicated the presence of C-F group which takes a major role in its antimicrobial activity **(Table 1)**[25,26,31].

In case of FTIR spectra of Carbopol934, there were prominent peaks for intramolecular hydrogen bonding, $\upsilon_{\mathbf{OH}}$ stretching vibration, carbonylic C=O and C-O stretching vibration and stretching vibration for the C-O-C, which confirmed the presence of acrylates **(Fig 4)**. The peak for out of plane bending vibration of =C-H was found between 850 and 800 cm^{-1} **(Table 2)**.

While comparing the FTIR spectra among the pure Norflox and C934, and the formulation containing both Norflox and C934, it is clear that the band position of C=O group has been affected by esterification and conjugation involving C=O group. Here, the stretching vibration of C=O in pure Norflox was found at 1700 cm^{-1}, which was lowered to 1650-1600 cm^{-1} in this formulation might be due to formation of β-ketoesters. The FTIR peaks assigned to $\upsilon_{C\text{-}O}$ and $\upsilon_{\mathbf{C\text{-}O\text{-}C}}$ represents acrylates and esters confirm the esterification between polymeric OH group and –COOH group of Norflox. The stretching vibration of C-F group remains nearly unaltered. Another probability of interaction is hydrogen bonding i.e., intermolecular hydrogen bonding due to prominent FTIR peaks between 3550 and 3400 cm^{-1}, and 2650 and 2500 cm^{-1} represented polymeric O-H...O-H…O-H and strong carboxylic OH hydrogen bonding, respectively. The hydrogen bonded -OH stretching vibration occurred over a wide range, 3550-2500 cm^{-1}. The bending vibration of O-H group showed medium to strong bands in the region around 1300-1250 cm^{-1}. The FTIR peak at 800 cm^{-1} suggested the probability of out of plane bending of –ene bond and m-substitution of $\delta_{Ar\text{-}H}$ hydrogen atom **(Table 3)**[25,26,30].

The C=O group of drug lowers the stretching vibration of C=O frequency indicating deprotonation and probably interaction of the said carboxylic C=O moiety with the polymer. However, a definitive conclusion about the keto group in the bonding to the polymer can be deduced because the corresponding band found from 1650 to 1600 cm^{-1} was due to probability of formation of β-ketoesters[36]. From the above data, it can be inferred that the carboxylic group of Norflox undergoes the interaction with the polymer, as would be expected chemically. Thus, the nitrogen atoms aren't likely to be involved in binding or the interaction. The nitrogen atom of the quinolone ring, 1-ortho to fluorine, is less electron rich due to electron deficient fluoroquinolone ring. In addition, ethyl and piperazinyl groups sterically hinder the reaction. The possibility of involvement of imino moiety of the piperazinyl group is also less prominent due to intense OH stretching vibration. The bands in the region 3550-2500 cm^{-1} could be assigned to the asymmetric and symmetric stretching vibrations of the OH groups of the inner and outer sphere of polymer. The shift in the characteristic bands of the FTIR spectra suggests change in their intensity, leading to the appearance of several absorbance bands of the asymmetric and symmetric stretching vibrations and overtone of the deformation vibrations. This indicates the confirmation of the hydrogen bonding[41]. By comparing the FTIR spectra among the pure drug, Carbopol polymer (C934) and the formulation containing both drug and polymer, FTIR peak of Norflox at 1700 cm^{-1} was not detected in the mucoadhesive system probably due to interaction with polymer. The missing peak was replaced with two very strong characteristic bands in the range of 1650-1600 cm^{-1} and at 1500-1450 cm^{-1}, which were assigned to $\upsilon_{(O\text{-}C\text{-}O)}$ asymmetric and symmetric stretching vibrations, respectively[26]. The difference Δ [$\upsilon_{(CO2)asym}$-$\upsilon_{(CO2)sym}$] is a useful characteristic for determining the involvement of the carboxylic group of Norflox. The Δ value for the interaction falls in the range of 183 - 250 cm^{-1} indicates the deprotonation of the carboxylic acid group and interaction between drug and polymer **(Table 1- 3)**[30].

In case of Raman spectra of Norflox, band at 485.6 cm^{-1} was assigned to the stretching vibration of ethyl group. The peak at 872.7 cm^{-1} represented stretching vibration of C-F group. The presence of carboxylic acid group was confirmed by $\upsilon_{O\text{-}C\text{-}O}$ and $\upsilon_{C=O}$ groups vibration at 1418.5 cm^{-1} and 1655.1 cm^{-1}, respectively **(Table 4a)**.

By comparing the Raman spectra of pure drug with the drug incorporated in the Carbopol suspension, the peak at 1418.5 cm^{-1}, assigned to the $\upsilon_{s\ O\text{-}C\text{-}O}$, is not prominent. Both symmetric and asymmetric stretching vibrations of O-C-O group are found in suspension containing C934. The Raman peak for stretching vibration of C=O is prominent in the suspension. From this it is clear that there is esterification reaction between Norflox and Carbopol polymer **(Table 4)**. The results of both FTIR and Raman spectra indicate that both the spectra show prominent peaks for the stretching vibration of O-C-O and C=O groups, which prove the formation of the esters between the drug and polymer. Moreover, both the intermolecular and polymeric hydrogen bonding are also prominent from the FTIR spectra of the formulation.

When an X-ray beam hits a sample and gets diffracted, we can measure the distances between the planes of the atoms that constitute the sample by applying Bragg's Law (Eq 1).

$$n\lambda = 2d\sin\theta \qquad (1)$$

where the integer *n* is the order of the diffracted beam, λ is the wavelength of the incident X-ray beam, *d* is the distance between adjacent planes of atoms (the *d*-spacings), and θ is the angle of incidence of the X-ray beam. Since we know λ and we can measure θ, we can calculate the *d*-spacings. The characteristic set of d-spacings generated in a typical X-ray scan provides a unique "fingerprint" of the drug molecule present in the sample. When properly interpreted, by comparing with pure drug as reference, this "fingerprint" allows for identification and change in crystallinity of drug present in the polymeric composites[42].

Table 5 and **6** give the data obtained for pure Norfloxacin and its formulation in terms of lattice spacing and relative peak intensities. Most of the characteristic peaks in the diffraction patterns were generally prominent and sharp, so measurement of the angles and hence of d-values was accurate. Proper sample preparation helped attain exact peak positions for qualitative analysis.

From the XRD patterns of both C934 it is clear that the polymer is fully amorphous in nature as there is no sharp prominent peaks **(Fig 10)**. From **Table 5** it has been confirmed that the three prominent peaks of both pure Norfloxacin and its formulation have different d-spacings corresponding to similar 2θ values. As the d-spacings of

the prominent XRD peaks of pure Norfloxacin are changed in XRD patterns of formulation, it can be concluded that the change in crystallinity of Norfloxacin in the formulation is due to rise in atomic densities in that particular plane of crystal lattice. From this we may predict that there could be change in orientation of crystal lattice due to incorporation of some extra atoms into it by esterification and hydrogen bonding.

It is known that Carbopol934 polymers are long-chained, high molecular-weight compounds containing active polyacrylic acid groups spaced along their length. This polymer promotes network like flocculation through adsorption of part of the chain on the surface of particle and the remaining part project out into the dispersion medium. Formation of bridge between the drug and projected parts leads to formation of floccules which retards sedimentation. This results in pseudoplastic flow in suspension that promotes the physical stability of suspension. Since our-SEM image analysis indicated that in the formulation maximum particles exhibited network like structure, this leads to produce pseudoplastic flow which provides supporting evidences for homogeneous, uniformly dispersed, pharmaceutically stable controlled release mucoadhesive Norfloxacin suspension[21].

Conclusions

On the basis of the above interpretation, it can be concluded that by preparing mucoadhesive suspension of Norfloxacin with C934 following a novel method of ultrasonication, there is a very good interaction between the carboxylic group of drug and hydroxyl group of polymer. This leads to esterification and intermolecular hydrogen bonding, by virtue of which a stable mucoadhesive suspension would be produced. From the XRD data supported by FTIR analysis, it appears that the crystalline form of pure Norflox under the experimental conditions resulted in little change in crystal habit of the drug. Moreover, size of the crystals was significantly influenced by intermolecular hydrogen bonding and esterification between Norflox and C934. The retention of crystallinity nature of the drug in the formulation may lead to increase in stability, decrease in solubility and delay in release of the drug from polymeric suspension. This may result in controlled release action of the formulation. Moreover, from the SEM image analysis, it may be concluded that the formulation containing Norflox and C934 was having maximum particles which exhibited network like structure. This leads to produce pseudoplastic flow which

provides supporting evidences for homogeneous, uniformly dispersed, pharmaceutically stable controlled release mucoadhesive Norfloxacin suspension.

The utility of the present work may be improved if the delivery rate, biodegradation and site-specific targeting of such controlled suspension would be properly monitored and controlled.
